Dear Reader:

The polar regions are very sensitive to environmental change, which makes their ice shields, neighboring lakes and oceans key targets for scientific drilling. In this volume of Scientific Drilling, we bring reports about the almost 4-km-deep ice coring in Antarctica (p. 41), which may reveal climate data back to around 1 Ma as well as environmental observations from a lake that has been isolated below the Antarctic ice shield for more than 20 Ma. An extraterrestrial impact in northeast Siberia 3.6 Ma ago created Lake El’gygytgyn, which recorded the onset of Northern Hemisphere glaciations within the lake’s oldest sediments, and traced within the younger sediments the ongoing waxing and waning of ice shields that persisted until today’s interglacial (p. 29).

Ocean gateways like that of the Bering Sea are key areas in understanding long-term climate change and heat transport to the poles. The Bering Sea—connected to the Arctic Ocean in the north through the narrow Bering Strait and to the Pacific Ocean in the south across the Aleutian Island arc—was sampled by IODP Expedition 323 (p. 4) to address paleo-water mass distribution, terrigenous sediment infill, sea-ice history and other environmental parameters extending back to 5 Ma or more.

Climate changes will impact all humans. However, a large part of Earth’s population lives in areas that are affected by the most rapid and unpredictable environmental change: earthquakes. Scientific drilling has taken on the challenge to understand the processes at depths where earthquakes take place, and in line with this, a summary of the San Andreas Fault Zone Observatory at Depth (SAFOD) is presented on page 14. The Dead Sea, lowest point on Earth, is a place where tectonism, climate change and history come together in the most fascinating way. On page 46 we offer a progress report on the attempt to unearth the environmental history of this unique location and how it may have impacted the civilization and the histories of the region.

As part of the preparations for the new International Ocean Discovery Program, planned to start from late 2013, the current IODP is preparing for the most ambitious ever ocean drilling effort—to drill through the entire ocean crust and into the underlying mantle. At a recent workshop funded by the Sloan Foundation (p. 51), the technical feasibility of this challenging endeavor was reviewed, and the science targets were expanded to include the presence of carbon throughout the crust and within the upper mantle. Other workshops addressed plans to drill back in ‘deep time’ (p. 66) to examine environments and conditions for life at 3,500 Ma, or to examine potential deep fault systems that have been active due to the removal of former ice shields during the recent interglacial (p. 56).

Scientific drilling has clearly taken on the fascinating challenges of understanding Earth systems. Please enjoy from your armchair what this issue has to offer.
